INTRODUCTION

The knowledge of the food and feeding habitats of a fish species is important to understand its role in the food chain and, consequently, the relationships with other species.

The study of the diet based on the analysis of stomach contents is a routine fish ecology proceeding.

Some simple studies on the feeding of the pouting (*Trisopterus luscus* L.) show that this gadoid is a strong predator since its larval form (LAST, 1978) and that adults choose mainly Crustacea (CHEVEY, 1930; OLIVER, 1949). Quantitative studies in different zones confirm these trends and show some variation in the diet with age (size or weight) of fish and with the time of the year (ARMSTRONG, 1979; LABARTA, 1976).

As a real contribution to the knowledge of the feeding habits and preferences of *T. luscus* in the North Coast of Portugal, we pay attention to the food of the pouting in this region. This attention is especially concerned to the relative importance in individual number and dry weight of the different prey groups, considering all fishes or dividing them in several size groups.

MATERIALS AND METHODS

During 1986, we examined 17 samples of *T. luscus* (908 individuals) from commercial trawling vessels operating in the North coast of Portugal. The fish was collected at the arrival of the boats and processed in the day of sampling. When this was not possible, the fish was frozen at once and processed not more than two weeks later. We took total length (cm) and weight (g) of all fishes. The aspect of fullness of the stomach was assessed and the ones with abundant and solid content were collected and stored in flasks with buffered 5 % formalin which also was injected in all 368 stomachs collected. In 48 hours, the gastric content was observed under a binocular stereoscopic microscope. The food items were identified (to the lowest taxonomical group possible), counted and joined in major taxonomic groups to determine dry weight (48 h at 105°C).

The variation of the diet with size of the prey was tested by dividing all fish in 3 length groups, supposed corresponding to age: «A» group (age 0 and I) < 19 cm, «B» group (age II and III) 19 to 27 cm, and «C» group (following age groups) > 27 cm, according to our interpretation of data from several authors as CHEVEY (1929), BENVENUE (1971), SOBRAL (1983), LABARTA Y FERREIRO (1982).

The feeding overlap of this 3 length groups was assessed by Kulczynski's similarity index (0-100), modified by Shorin (LABARTA, 1976): $F_c = \inf (Rip, Riq)$.

It was calculated too:

- frequency of prey group i — $f = ni/e$
- abundance per stomach of prey group i — $Nm = ni/ei$
- relative abundance of prey group i (to N) — $Ri = 100 ni/N$
- frequency of occurrence — $P = 100 ei/e$
- stomach vacuity coefficient — $V = 100 ev/E$

with:

N = total number of prey items
 ni = number of prey items from taxonomic group i
 e = number of stomachs analysed for each size group
 ei = number of stomachs containing taxonomic group i
 ev = number of empty stomachs
 E = total number of observed fish

(LABARTA, 1976; HYNES, 1950; HYSLOP, 1980).

RESULTS

1 — Vacuity coefficient along the year

From the 908 observed individuals, 149 had empty stomachs. The annual variation of the vacuity coefficient (see table 1) shows little changes, with a maximum of 24.6 %, a minimum of 7 % and a mean value of 16.2 ± 5.7 %.

2 — The food in numbers

Taking all the individuals which stomachs were analysed and considering relative abundance of broad taxonomic groups of prey items (see table 1 and fig. 1), we found that Crustacea is the most important one (73.3 %) in the food of the pouting. Fish is the second major group (16.4 %) followed by Annelida (5.4 %), Mollusca (3.1 %) and Echinodermata (1.7 %). Considering frequency of occurrence (see table 2), the most frequent groups are Crustacea (84.5 %) and Teleostei (45.1 %), followed by Annelida (23.4 %), Mollusca (12.5 %) and Echinodermata (7.6 %).

Detailing (see table 2), the prey items which more importance in Crustacea (with higher values of f, Ri and P) are Carididae, Brachyura, Galateidae and Amphipoda. In Mollusca,

TABLE 1 — *Trisopterus luscus* diet variation (in number of preys and in mg dry weight) in 1986. AN — Annelids; EQ — Echinodermata; MO — Molluscs; CR — Crustacea; TE — Teleosts. E — Total fish observed; e — collected; stomachs; ev — empty stomachs; V — vacuity coefficient

Cephalopoda are the most important items and in the Teleostei, Blenniidae are the fishes which more importance, mainly the species *Lesueuria friesii*.

Fig. 1 — Relative abundance of prey groups in *T. luscus* diet. See table 1 for labels

Considering the number of individuals per stomach (Nm) some groups of Crustacea are well represented, as Galateidae (4.56), Schizopoda (3.83) and Carididae (3.22), all them with more than three individuals per stomach.

3 — The food in weight

By pooling the content (dry weight) of all stomachs in broad taxonomic groups, we found that the major contributor in weight (see table 1 and fig. 2) to the diet is the Teleostei group (53.04 %), followed by Crustacea (38.98 %). The other groups, Annelida (5.57 %), Mollusca (1.64 %) and Echinodermata (0.77 %) have small importance.

4 — Diet variation with the size of *T. luscus*

Table 2 and fig. 3 show that the three size groups have no great variations in what concerns Annelida, Echinodermata and Mollusca.

TABLE 2—*Trisopterus luscus* diet variation (in numbers) for three size groups. N—total number of preys in each size group; ni—number of preys of taxonomic group; e—number of analysed stomachs; ei—number of stomachs with taxonomic group; f=ni/e abundance of prey group; f=ni/e abundance of prey group; P=100 ni/N relative abundance of prey group i (to N); P=100 ei/e frequency of occurrence

For Teleostei, inversely, there is an increase in relative abundance for bigger fish sizes (5.86; 19.62 and 36.42 respectively for A, B and C groups).

[illegible]

With the increase in the size of the predator, there is a decrease in the diversity of the different groups of Crustacea (9, 7 and 5 groups respectively for A, B and C groups). There are less Crustacea groups, for bigger size of the predator, that show high values of frequency of occurrence: in A group, the important prey groups are Carididae, Galateidae and Amphipoda; in B group only Carididae and Brachyura are important, the others having little importance; in C group only Carididae and Brachyura are significant. Remarkable is the increasing importance of Brachyura as predator increases in size.

TABLE 4 — Kulczynski's similarity index, showing the feeding overlap of three size groups of *T. luscus*. A — < 19 cm; B — 19-27 cm; C — > 27 cm

	B	C
A	74.25	53.27
B	—	71.17

In Teleostei, note higher values for Pleuronectids as the pouting grows.

Table 3 and fig. 4 show that, for bigger fish, the percent of weight of each prey group per stomach increases for Teleostei and decreases for Crustacea. Less clear is the decrease for Annelida and Mollusca. Echinodermata have little importance in all size groups. In bigger fish, the diet is almost exclusively composed by Teleostei (69.86 %) and Crustacea (26.19 %).

Comparing the diet of the three size groups (A, B and C) by the feeding overlap index, we obtained the values of table 4.

We can see that the feeding overlap of the three groups is high (over 50), the groups A and C having the lower value (53.27) and the other groups values over 70 (A-B 74.25 and B-C 71.17).

Fig. 4 — Comparison of *T. luscus* diet considering three size groups of this predator (see fig. 3) and dry weight

CONCLUSIONS AND DISCUSSION

As conclusions, we can emphasize the following ones:

1. The rhythm of sazonal feeding, as assessed by the vacuity coefficient, doesn't show any period of reduction of feeding activity.
2. Taking all sizes of the pouting, the dominant groups (relative abundance) in the diet, are Crustacea (73.3 %) and Teleostei (16.4 %) if we consider the number of prey items. Considering the food in weight, the results are reversed, being Teleostei (53.04 %) the dominant group and Crustacea the second one (38.98 %).
3. Annelida, Echinodermata and Mollusca representation in the diet, in numbers or weight, is always low.

The prey groups found here are similar to those identified by LABARTA (1976) to the pouting from Galicia (Northwest of

Spain). The main differences are the absence of Euphausiacea and Copepoda in our results. Also the prey lists presented by BENVEGNI (1971) and by SYMONDS and ELSON (1983) show similarity with our results. On the other hand, the ones presented by OLIVER (1949) are not very clear, and consequently difficult to compare.

In our results, the importance of the Homaridae group, namely *Nephrops norvegicus* is not significant. This is a contrast with ARMSTRONG (1979) results, probably because this author investigated areas of great abundance of this prey species.

4. The feeding overlap index shows that the three size groups have similar diet. However, we can verify an increase in the importance of Teleostei and a decrease of the other groups, for bigger fishes.

Similar evolution was observed in other gadoids by POWLES (1958) and, less clearly, in *T. luscus* by ARMSTRONG (1979).

Research on the food of individuals less than 13 cm is needed to have a more complete picture of the diet of this specie. However, this is not possible by utilising commercial catches.

APPENDIX

Taxonomic groups identified in stomach contents

ANNELIDA	GALATEIDAE
ECHINODERMATA	
HOLOTHURIOIDEA	<i>Galatea strigosa</i>
ECHINOIDEA	ANOMURA
OFIUROIDEA	<i>Pagurus</i> sp.
MOLLUSCA	BRACHYURA
LAMELLIBRANCHIATA	<i>Carcinus</i> sp.
GASTROPODA	<i>Macropipus depurator</i>
<i>Cardium</i> sp.	<i>Macropodia rostrata</i>
CEPHALOPODA	<i>Inachus dorsetensis</i>
<i>Octopus vulgaris</i>	<i>Portunus</i> sp.
<i>Sepia officinalis</i>	<i>Ebalia</i> sp.
<i>Loligo</i> sp.	<i>Polibius</i> sp.

CRUSTACEA	Xanto sp.
ISOPODA	<i>Goneplax rhomboides</i>
AMPHIPODA	<i>Eurinome</i> sp.
STOMATOPODA	TELEOSTEI
<i>Squilla</i> sp.	<i>Merluccius</i> sp.
SCHIZOPODA	<i>Lesueurina friesii</i>
Mysis sp.	<i>Sardina pilchardus</i>
CARIDIDAE	<i>Trachurus trachurus</i>
<i>Palaemon</i> sp.	<i>Belone belone</i>
HOMARIDAE	TRICHIURIDAE
<i>Nephrops norvegicus</i>	PLEURONECTIFORMES

SUMMARY

The pouting (*Trisopterus luscus* L.) is an important fish in fisheries in the North of Portugal. The objectives of this work were to study the diet of the adult stage of this species in order to clarify its position in the food chain and its ecological niche, to know if and how the diet changes with the size of the fish and finally to get more data about the organisms living in our waters.

During 1986, 908 individuals obtained from commercial vessels based in the North Coast of Portugal were examined. There were collected 368 stomachs and their content were identified, counted and weighed. It was calculated the frequency, relative abundance, abundance per stomach and frequency of occurrence of prey items. Stomach vacuity coefficient index was also calculated. The comparison of the diet of different size groups was assessed by Kulczynski's similarity index.

The main results obtained (by pooling all the samples) were: considering the number of preys and relative abundance, it was found Crustaceae (73.3 %), Teleostei (16.4 %), Annelida (5.4 %), Mollusca found Teleostei (53 %), Crustaceae (39 %), Annelida (5.6 %), Mollusca (1.6 %) and Echinodermata (0.8 %).

It was found that, in adult fishes, the size of this predator has considerable effect on the choice of preys. For bigger fish, the importance of Teleostei in the diet increased and, on the contrary, the importance of Crustaceae, Mollusca, Annelida and Echinodermata decreased. The feeding overlap of three size groups, as assessed by the Kulczynski's similarity index is high. The pair A-C with the lower value, 53.3, having the other pairs A-B, 74.3 and B-C, 71.2.

From the 908 observed individuals, 149 had empty stomach. The annual variation of vacuity coefficient shows little changes, 16.2 % + / - 5.7, pointing out no reduction on feeding activity, either in summer or winter.

ACKNOWLEDGEMENTS

I wish to thank to Prof. Dr. M. Cruz for all help during this work. To the Directors of Instituto Nacional de Investigações Pesqueiras (Centro de Matosinhos) — Dr.^a E. Rebordão and Dr. M. Sobral — who supplied the fish and facilities, and to all the staff, I wish to thank.
